

Biomonitoring: Polybrominated Diphenyl Ethers (PBDEs)

Methods

Indicator

B8. PBDEs in women ages 16 to 49 years: Median concentrations in blood serum, by race/ethnicity and family income, 2003-2004.

Summary

Since the 1970s, the National Center for Health Statistics, a division of the Centers for Disease Control and Prevention, has conducted the National Health and Nutrition Examination Surveys (NHANES), a series of U.S. national surveys of the health and nutrition status of the noninstitutionalized civilian population. The National Center for Environmental Health at CDC measures environmental chemicals in blood and urine samples collected from NHANES participants.¹ This indicator uses serum PBDE measurements of 10 PBDE congeners in women ages 16 to 49 years, summed to give the total serum PBDE. The NHANES 2003-2004 survey included serum PBDE data for children and adults ages 12 years and over. Indicator B8 gives the median concentrations of total serum PBDE for women ages 16 to 49 years for 2003-2004, stratified by race/ethnicity and by family income. The median is the estimated concentration such that 50% of all noninstitutionalized civilian women ages 16 to 49 years during the survey period have total serum PBDE concentrations below this level; the population distribution was adjusted by age-specific birth rates to estimate the median prenatal exposure to PBDEs. Table B8a presents the median concentrations of total serum PBDE for children ages 12 to 17 years for 2003-2004, stratified by race/ethnicity and by family income. The survey data were weighted to account for over-sampling, non-response, and non-coverage.

Data Summary

Indicator	B8. PBDEs in women ages 16 to 49 years: Median concentrations in blood serum, by race/ethnicity and family income, 2003-2004.
Time Period	2003-2004
Data	Serum PBDE for ten PBDE congeners.
Limits of Detection*	Limits of detection varied among the ten congeners and among the measurements of each congener.
Number of values	626
Number of Non-missing Values**	540 (86%)
Number of Missing Values**	86 (14%)
Percentage Below Limit of Detection***	BDE-47: 1%. BDE-99: 26%. BDE-100: 3%. BDE-153: 6%. Any one of 10 PBDE congeners: 97%

¹ Centers for Disease Control and Prevention. 2009. Fourth National Report on Human Exposure to Environmental Chemicals. Atlanta, GA. Available at: www.cdc.gov/exposurereport.

Biomonitoring: Polybrominated Diphenyl Ethers (PBDEs)

* The Limit of Detection (LOD) is defined as the level at which the measurement has a 95% probability of being greater than zero.

**Non-missing values include those below the analytical LOD, which are reported as $LOD/\sqrt{2}$. Includes samples with one or more non-missing congeners. 502 sampled women 16 to 49 years had non-missing values for all 10 PBDE congeners measured in NHANES. Missing values are the number of sampled women ages 16 to 49 years in the Mobile Examination Center (MEC) sub-sample that have no value reported for all 10 PBDE congeners.

***This percentage is survey-weighted using the NHANES MEC survey weights for the given period and is weighted by age-specific birth rates.

Overview of Data Files

The following files are needed to calculate this indicator. The files together with the survey documentation and SAS programs for reading in the data are available at the NHANES website:

<http://www.cdc.gov/nchs/nhanes.htm>.

- NHANES 2003-2004: Demographic file demo_c.xpt. PBDE Laboratory file l28pbe_c.xpt. The demographic file demo_c.xpt is a SAS transport file that contains the subject identifier (SEQN), age (RIDAGEYR), race/ethnicity (RIDRETH1), poverty income ratio (INDFMPIR), pseudo-stratum (SDMVSTRA) and the pseudo-PSU (SDMVPSU). The PBDE laboratory file l28pbe_c.xpt contains SEQN, the ten lipid-adjusted PBDE congeners (LBXBR1LA to LBXBR9LA and LBXBR66L), the ten PBDE non-detect comment codes (LBXBR1LC to LBXBR9LC and LBXBR66C), and the two-year sub-sample B Mobile Examination Center (MEC) weight (WTSB2YR). The two files are merged using the common variable SEQN.

National Health and Nutrition Examination Surveys (NHANES)

Since the 1970s, the National Center for Health Statistics, a division of the Centers for Disease Control and Prevention, has conducted the National Health and Nutrition Examination Surveys (NHANES), a series of U.S. national surveys of the health and nutrition status of the noninstitutionalized civilian population. The National Center for Environmental Health at CDC measures environmental chemicals in blood and urine samples collected from NHANES participants. This indicator uses serum PBDE measurements of ten congeners from NHANES 2003-2004 in women ages 16 to 49. Table B8a uses serum PBDE measurements of ten congeners from NHANES 2003-2004 in children ages 12 to 17. The NHANES data were obtained from the NHANES website: <http://www.cdc.gov/nchs/nhanes.htm> Following the CDC recommended approach, values below the analytical limit of detection (LOD) were replaced by $LOD/\sqrt{2}$.ⁱⁱ

The ten PBDE congeners measured in NHANES 2003-2004 are listed in the following table together with their SAS variable names:

BDE Code	Full name	SAS name (lipid-adjusted)	SAS name for non-detect comment code*
BDE-17	2,2',4-	LBXBR1LA	LBXBR1LC

ⁱⁱ See Hornung RW, Reed LD. 1990. Estimation of average concentration in the presence of nondetectable values. *Applied Occupational and Environmental Hygiene* 5:46-51.

Biomonitoring: Polybrominated Diphenyl Ethers (PBDEs)

BDE Code	Full name	SAS name (lipid-adjusted)	SAS name for non-detect comment code*
	tribromodiphenyl ether		
BDE-28	2,4,4'-tribromodiphenyl ether	LBXBR2LA	LBXBR2LC
BDE-47	2,2',4,4'-tetrabromodiphenyl ether	LBXBR3LA	LBXBR3LC
BDE-85	2,2',3,4,4'-pentabromodiphenyl ether	LBXBR4LA	LBXBR4LC
BDE-99	2,2',4,4',5'-pentabromodiphenyl ether	LBXBR5LA	LBXBR5LC
BDE-100	2,2',4,4',6'-pentabromodiphenyl ether	LBXBR6LA	LBXBR6LC
BDE-153	2,2',4,4',5,5'-hexabromodiphenyl ether	LBXBR7LA	LBXBR7LC
BDE-154	2,2',4,4',5,6'-hexabromodiphenyl ether	LBXBR8LA	LBXBR8LC
BDE-183	2,2',3,4,4',5',6'-heptabromodiphenyl ether	LBXBR9LA	LBXBR9LC
BDE-66	2,3',4,4'-tetrabromodiphenyl ether	LBXBR66L	LBXBR66C

*The nondetect comment code equals 1 if the measurement is below the analytical limit of detection, and equals 0 if the measurement is at or above the analytical limit of detection.

This analysis uses the sum of the ten PBDE congeners listed in this table. If some but not all of the congeners are missing, then the sum is over the non-missing congeners.

The NHANES use a complex multi-stage, stratified, clustered sampling design. Certain demographic groups were deliberately over-sampled, including Mexican-Americans and Blacks, to increase the reliability and precision of estimates of health status indicators for these population subgroups. The publicly released data includes survey weights to adjust for the over-sampling, non-response, and non-coverage. The statistical analyses used the applicable MEC survey weights (WTSB2YR) to re-adjust the serum PBDE data to represent the national population.

Biomonitoring: Polybrominated Diphenyl Ethers (PBDEs)

Age-Specific Birth Rates

In addition to the NHANES MEC survey weights, the data for women of child-bearing age (ages 16 to 49) were also weighted by the birth rate for women of the given age and race/ethnicity to estimate prenatal exposures. Thus the overall weight is the product of the NHANES survey weight and the total number of births in 2003 and 2004 for the given age and race/ethnicity, divided by twice the corresponding population of women at the midpoint of 2003-2004.ⁱⁱⁱ

Adjusted Survey Weight =

MEC survey weight \times U.S. Births (NHANES cycle, age, race/ethnicity) /
{Number of years in NHANES cycle \times U.S. Women (NHANES cycle midpoint, age, race/ethnicity)}.

Race/Ethnicity and Family Income

For this indicator, the percentiles were calculated for demographic strata defined by the race/ethnicity and family income.

The family income was characterized based on the INDFMPIR variable, which is the ratio of the family income to the poverty level. The National Center for Health Statistics used the U.S. Census Bureau Current Population Survey definition of a “family” as “a group of two people or more (one of whom is the householder) related by birth, marriage, or adoption and residing together” to group household members into family units, and the corresponding family income for the respondent was obtained during the interview. The U.S. Census Bureau defines annual poverty level money thresholds varying by family size and composition. The poverty income ratio (PIR) is the family income divided by the poverty level for that family. Family income was stratified into the following groups:

- Below Poverty Level: $PIR < 1$
- Above Poverty Level: $PIR \geq 1$
- Unknown Income: PIR is missing

For the two year period 2003-2004, the weighted percentage of women ages 16 to 49 years with unknown income was 6%.

Race/ethnicity was characterized using the RIDRETH1 variable. The possible values of this variable are:

- 1. Mexican American
- 2. Other Hispanic
- 3. Non-Hispanic White
- 4. Non-Hispanic Black
- 5. Other Race – Including Multi-racial

ⁱⁱⁱ Axelrad, D.A., Cohen, J. 2010. Calculating summary statistics for population chemical biomonitoring in women of child-bearing age with adjustment for age-specific natality. *Environmental Research* 111 (1) 149-155.

Biomonitoring: Polybrominated Diphenyl Ethers (PBDEs)

- “.” Missing

Category 5 includes: all Non-Hispanic single race responses other than White or Black; and multi-racial responses.

For indicator B8, the RIDRETH1 categories 2, 5, and missing were combined into a single “All Other Races/Ethnicities” category. This produced the following categories:

- White non-Hispanic: RIDRETH1 = 3
- Black non-Hispanic: RIDRETH1 = 4
- Mexican-American: RIDRETH1 = 1
- All Other Races/Ethnicities: RIDRETH1 = 2 or 5 or missing

The “All Other Races/Ethnicities” category includes multiracial persons and individuals whose racial or ethnic identity is not White non-Hispanic, Black non-Hispanic, or Mexican-American. Persons of “All Other Races/Ethnicities” are selected into the survey with a probability that is very much lower than White non-Hispanic, Black non-Hispanic and Mexican-American individuals, and as a group they are not representative of all other race and ethnicities in the United States.

Calculation of Indicator

Indicator B8 is the median for total serum PBDE in women of ages 16 to 49 years, stratified by race/ethnicity or family income. Table B8a presents the median for total serum PBDE in children of ages 12 to 17 years, stratified by race/ethnicity or family income. The median is the estimated concentration such that 50% of all noninstitutionalized civilian women ages 16 to 49 years during the survey period have total serum PBDE concentrations below this level. To adjust the NHANES data to represent prenatal exposures, the data for each woman surveyed was multiplied by the estimated number of births per woman of the given age and race/ethnicity. Note that the calculations for Indicator B8 also apply to Table B8a, except that for children the birth rate adjustment is not applied.

To simply demonstrate the calculations, we will use the NHANES 2003-2004 total serum PBDE values for women ages 16 to 49 years as an example. We have rounded all the numbers to make the calculations easier:

We begin with all the non-missing NHANES 2003-2004 total serum PBDE values for women ages 16 to 49 years. Assume for the sake of simplicity that valid data on total serum PBDE were available for every sampled woman. Each sampled woman has an associated survey weight WTSB2YR that estimates the annual number of U.S. women represented by that sampled woman. Each sampled woman also has an associated birth rate giving the numbers of births per woman of the given age, race, and ethnicity. The product of the survey weight and the birth rate estimates the annual number of U.S. births represented by that sampled woman, which we will refer to as the adjusted survey weight. For example, the lowest total serum PBDE measurement for a woman between 16 and 49 years of age is 6.5 ng/g lipid with a survey weight of 20,000, a birth rate of 0.1, and thus an adjusted survey weight of 2,000, and so represents 2,000 births. The

Biomonitoring: Polybrominated Diphenyl Ethers (PBDEs)

total of the adjusted survey weights for the sampled women equals 4 million, the total number of U.S. births to women ages 16 to 49 years. The second lowest measurement is 6.8 ng/g lipid with an adjusted survey weight of 3,000, and so represents another 3,000 U.S. births. The highest measurement was 2260.5 ng/g lipid, with an adjusted survey weight of 2,000, and so represents another 2,000 U.S. births.

To calculate the median, we can use the adjusted survey weights to expand the data to the entire U.S. population of births to women ages 16 to 49. We have 2,000 values of 6.5 ng/g lipid from the lowest measurement, 3,000 values of 6.8 ng/g lipid from the second lowest measurement, and so on, up to 2,000 values of 2260.5 ng/g lipid from the highest measurement. Arranging these 4 million values in increasing order, the 2 millionth value is 44.2 ng/g lipid $\mu\text{g/dL}$. Since half of the values are below 44.2 and half of the values are above 44.2, the median equals 44.2 ng/g lipid.

In reality, the calculations need to take into account that total serum PBDE measurements were not available for every respondent, and to use exact rather than rounded numbers. There were total serum PBDE measurements for only 540 of the 626 sampled women ages 16 to 49 years. The adjusted survey weights for all 626 sampled women add up to 4.1 million, the U.S. population of births to women ages 16 to 49. The adjusted survey weights for the 540 sampled women with total serum PBDE data add up to 3.7 million. Thus the available data represent 3.7 million values and so represent only 90% of the U.S. population of births. The median is given by the 1.85 millionth (50% of 3.7 million) U.S. birth's value. These calculations assume that the sampled women with valid total serum PBDE data are representative of women giving birth without valid total serum PBDE data. The calculations also assume that the sampled women are representative of women that actually gave birth in 2003-2004, since NHANES information on pregnancy and births was not incorporated into the analysis.

Equations

These percentile calculations can also be given as the following mathematical equations, which are based on the default percentile calculation formulas from Statistical Analysis System (SAS) software. Exclude all missing total serum PBDE values. Suppose there are n women of ages 16 to 49 years with valid total serum PBDE values. Arrange the total serum PBDE concentrations in increasing order (including tied values) so that the lowest concentration is $x(1)$ with an adjusted survey weight of $w(1)$, the second lowest concentration is $x(2)$ with an adjusted survey weight of $w(2)$, ..., and the highest concentration is $x(n)$ with a adjusted survey weight of $w(n)$.

1. Sum all the adjusted survey weights to get the total weight W :

$$W = \sum[1 \leq i \leq n] w(i)$$

2. Find the largest number i so that the total of the weights for the i lowest values is less than or equal to $W/2$.

$$\sum[j \leq i] w(j) \leq W/2 < \sum[j \leq i + 1] w(j)$$

Biomonitoring: Polybrominated Diphenyl Ethers (PBDEs)

3. Calculate the median using the results of the second step. We either have

$$\Sigma[j \leq i] w(j) = W/2 < \Sigma[j \leq i + 1] w(j)$$

or

$$\Sigma[j \leq i] w(j) < W/2 < \Sigma[j \leq i + 1] w(j)$$

In the first case we define the median as the average of the i 'th and $i + 1$ 'th values:

$$\text{Median} = [x(i) + x(i + 1)]/2 \text{ if } \Sigma[j \leq i] w(j) = W/2$$

In the second case we define the median as the $i + 1$ 'th value:

$$\text{Median} = x(i + 1) \text{ if } \Sigma[j \leq i] w(j) < W/2$$

(The estimated median does not depend upon how the tied values of $x(j)$ are ordered).

Relative Standard Error

The uncertainties of the median values were calculated using a revised version of the CDC method given in CDC 2005^{iv}, Appendix C, and the SAS® program provided by CDC. The method uses the Clopper-Pearson binomial confidence intervals adapted for complex surveys by Korn and Graubard (see Korn and Graubard, 1999^v, p. 65). The following text is a revised version of the Appendix C. For the birth rate adjusted calculations for women ages 16 to 49, the sample weight is adjusted by multiplying by the age-specific birth rate.

Step 1: Use SAS® Proc Univariate to obtain a point estimate P_{SAS} of the percentile value. Use the Weight option to assign the exact correct sample weight for each chemical result.

Step 2: Use SUDAAN® Proc Descript with Taylor Linearization DESIGN = WR (i.e., sampling with replacement) and the proper sampling weight to estimate the proportion (p) of subjects with results less than and not equal to the percentile estimate P_{SAS} obtained in Step 1 and to obtain the standard error (se_p) associated with this proportion estimate. Compute the degrees-of-freedom adjusted effective sample size

$$n_{df} = (t_{num}/t_{denom})^2 p(1 - p) / (se_p)^2$$

where t_{num} and t_{denom} are 0.975 critical values of the Student's t distribution with degrees of freedom equal to the sample size minus 1 and the number of PSUs minus the number of strata, respectively. Note: the degrees of freedom for t_{denom} can vary with the demographic sub-group of interest.

Step 3: After obtaining an estimate of p (i.e., the proportion obtained in Step 2), compute the Clopper-Pearson 95% confidence interval ($P_L(x, n_{df}), P_U(x, n_{df})$) as follows:

$$P_L(x, n_{df}) = v_1 F_{v_1, v_2}(0.025) / (v_2 + v_1 F_{v_1, v_2}(0.025))$$

^{iv} CDC Third National Report on Human Exposure to Environmental Chemicals. 2005

^v Korn E. L., Graubard B. I. 1999. *Analysis of Health Surveys*. Wiley.

Biomonitoring: Polybrominated Diphenyl Ethers (PBDEs)

$$P_U(x, n_{df}) = v_3 F_{v_3, v_4}(0.975) / (v_4 + v_3 F_{v_3, v_4}(0.975))$$

where x is equal to p times n_{df} , $v_1 = 2x$, $v_2 = 2(n_{df} - x + 1)$, $v_3 = 2(x + 1)$, $v_4 = 2(n_{df} - x)$, and $F_{d1, d2}(\beta)$ is the β quantile of an F distribution with $d1$ and $d2$ degrees of freedom. (Note: If n_{df} is greater than the actual sample size or if p is equal to zero, then the actual sample size should be used.) This step will produce a lower and an upper limit for the estimated proportion obtained in Step 2.

Step 4: Use SAS Proc Univariate (again using the Weight option to assign weights) to determine the chemical percentile values P_{CDC} , L_{CDC} and U_{CDC} that correspond to the proportion p obtained in Step 2 and its lower and upper limits obtained in Step 3. Do not round the values of p and the lower and upper limits. For example, if $p = 0.4832$, then P_{CDC} is the 48.32'th percentile value of the chemical. The alternative percentile estimates P_{CDC} and P_{SAS} are not necessarily equal.

Step 5: Use the confidence interval from Step 4 to estimate the standard error of the estimated percentile P_{CDC} :

$$\text{Standard Error } (P_{CDC}) = (U_{CDC} - L_{CDC}) / (2t_{denom})$$

Step 6: Use the estimated percentile P_{CDC} and the standard error from Step 4 to estimate the relative standard error of the estimated percentile P_{CDC} :

$$\text{Relative Standard Error } (\%) = [\text{Standard Error } (P_{CDC}) / P_{CDC}] \times 100 \%$$

The tabulated estimated percentile is the value of P_{SAS} given in Step 1. The relative standard error is given in Step 6, using P_{CDC} and its standard error.

The relative standard error depends upon the survey design. For this purpose, the public release version of NHANES includes the variables $SDMVSTRA$ and $SDMVPSU$, which are the Masked Variance Unit pseudo-stratum and pseudo-primary sampling unit (pseudo-PSU). For approximate variance estimation, the survey design can be approximated as being a stratified random sample with replacement of the pseudo-PSUs from each pseudo-stratum; the true stratum and PSU variables are not provided in the public release version to protect confidentiality. If the relative standard error is too high, then the estimated percentile will not be accurately estimated. Furthermore, if the degrees of freedom (from Step 2) is too low, then the relative standard error will be less accurately estimated and thus may be underestimated. For these reasons, percentiles with high relative standard errors or with low degrees of freedom are unstable or unreliable.

Percentiles with a relative standard error less than 30% and with 12 or more degrees of freedom were treated as being reliable and were tabulated. Percentiles with a relative standard error that is 30% or greater but less than 40% and with 12 or more degrees of freedom were treated as being unstable; these values were tabulated but were flagged to be interpreted with caution. Percentiles with a relative standard error less than 40% and with between 7 and 11 degrees of freedom were also treated as being unstable; these values were tabulated but were flagged to be interpreted with caution. Percentiles with a relative standard error that is 40% or greater, or without an estimated relative standard error, or with 6 or less degrees of freedom, were treated as being unreliable; these values were not tabulated and were flagged as having a large uncertainty.

Questions and Comments

Questions regarding these methods, and suggestions to improve the description of the methods, are welcome. Please use the “Contact Us” link at the bottom of any page in the America’s Children and the Environment website.

Biomonitoring: Polybrominated Diphenyl Ethers (PBDEs)

Statistical Comparisons

Statistical analyses of the percentiles were used to determine whether the differences between percentiles for different demographic groups were statistically significant. For these analyses, the percentiles and their standard errors were calculated for each combination of age group, sex (in the cases of children), income group (below poverty, at or above poverty, unknown income), and race/ethnicity group using the method described in the “Relative Standard Error” section. In the notation of that section, the percentile and standard error are the values of P_{CDC} and Standard Error (P_{CDC}), respectively. These calculated standard errors account for the survey weighting and design and, for women, for the age-specific birth rate.

Using a weighted linear regression model, the percentile was assumed to be the sum of explanatory terms for age, sex, income and/or race/ethnicity and a random error term; the error terms were assumed to be approximately independent and normally distributed with a mean of zero and a variance equal to the square of the standard error. In this model, the weight is the inverse of the variance, so that percentiles with larger standard errors are given less of a statistical weight in the fitted regression model. Using this model, the difference in the value of a percentile between different demographic groups is statistically significant if the difference between the corresponding sums of explanatory terms is statistically significantly different from zero. A p-value at or below 0.05 implies that the difference is statistically significant at the 5% significance level. No adjustment is made for multiple comparisons.

For each type of comparison, we present unadjusted and adjusted analyses. The unadjusted analyses directly compare a percentile between different demographic groups. The adjusted analyses add other demographic explanatory variables to the statistical model and use the statistical model to account for the possible confounding effects of these other demographic variables. For example, the unadjusted race/ethnicity comparisons use and compare the percentiles between different race/ethnicity pairs. The adjusted race/ethnicity comparisons use the percentiles for each age/sex/income/race/ethnicity combination. The adjusted analyses add age, sex, and income terms to the statistical model and compare the percentiles between different race/ethnicity pairs after accounting for the effects of the other demographic variables. For example, if White non-Hispanics tend to have higher family incomes than Black non-Hispanics, and if the serum PBDE level strongly depends on family income only, then the unadjusted differences between these two race/ethnicity groups would be significant but the adjusted difference (taking into account income) would not be significant.

Comparisons between pairs of race/ethnicity groups are shown in Table 1 for women ages 16 to 49 years and in Table 3 for children ages 12 to 17 years. Comparisons between income groups are shown in Table 2 for women ages 16 to 49 years and in Table 4 for children ages 12 to 17 years. In Tables 1 and 3, for the unadjusted “All incomes” comparisons, the only explanatory variables are terms for each race/ethnicity group. For these unadjusted comparisons, the statistical tests compare the percentiles for each pair of race/ethnicity groups. For the adjusted “All incomes (adjusted for age, sex, income)” comparisons, the explanatory variables are terms for each race/ethnicity group together with terms for each age, sex (for children), and income group. For these adjusted comparisons, the statistical test compares the pair of race/ethnicity groups after accounting for any differences in the age, sex (for children) and income distributions

Biomonitoring: Polybrominated Diphenyl Ethers (PBDEs)

between the race/ethnicity groups. The adjustment for sex is applicable only for children, and thus appears only in Tables 3 and 4.

In Tables 2 and 4, the unadjusted p-value for the population “All” compares the percentiles for women ages 16 to 49 years or children ages 12 to 17 years below poverty level with those at or above poverty level, using the explanatory variables for the two income groups (below poverty, at or above poverty), excluding those with unknown income. The adjusted p-value includes adjustment terms for age, sex (for children), and race/ethnicity in the model.

For women, the age groups used were 16-19, 20-24, 25-29, 30-39, and 40-49. For children, the age groups used were 12-14 and 15-17.

For more details on these statistical analyses, see the memorandum by Cohen (2010).^{vi}

Table 1. Statistical significance tests comparing the percentiles of PBDEs in women ages 16 to 49 years, between pairs of race/ethnicity groups, for 2003-2004.

Variable	Percentile	First race/ethnicity group	Second race/ethnicity group*	P-VALUES	
				All incomes	All incomes (adjusted for age, income)
